

## COSE222: Computer Architecture Assignment #3

Due: Nov 29, 2020 (Sunday) 11:59pm on Blackboard

Solutions (Total score: 219)

Please answer for the questions. Write your student ID and name on the top of the document. Submit your homework with “PDF” format only. (You can easily generate the pdf files from Microsoft Word or HWP. You can also handwrite your answers to scan the handwritten documents with “PDF” format. You may use the document capture applications such as “Office Lens” for scanning your documents with your smartphones.)

The answer rules:

- (1) You can write answers in both Korean and English.
- (2) Please make your final answer numbers have two decimal places.
- (3) Performance of A is improved by  $NN\%$  compared to performance B if  $\text{PerfA} / \text{PerfB} = 1.NN$ .

The following figure shows the RISC-V single-cycle processor covered during the classes.

Figure 1. RISC-V single-cycle processor

1. Consider the following instruction mix: (I-type means instructions that use *immediate* data)

R-type	I-type (non-ld)	Load	Store	Branch	Jump
27%	23%	20%	15%	11%	4%

(a) What fraction of all instructions use data memory? [5]

Memory instructions (Load + Store) access data memory. Thus  $20 + 15 = 35\%$

(b) What fraction of all instructions use instructions memory? [5]

All instructions access the instruction memory since all instructions are fetched from the instruction memory. Therefore 100%

(c) What fraction of all instructions use the sign extend? [5]

Only R-type instructions do not use the sign extend. 73%

(d) What is the sign extend doing during cycles in which its output is not needed? [5]

The sign extend logic produces an output during every cycle. If its output is not necessary it is simply ignored.

2. For the single-cycle processor design, we do *NOT* consider I-type instructions such as `addi` and `andi`. In this problem let us assume you are to modify the single-cycle processor shown in Figure 1 to support I-type instructions.

(a) What additional logic blocks, if any, are needed to add I-type instructions to the single-cycle processor shown in Figure 1? List any required logic blocks and explain their purpose. [5]

No additional logic blocks are needed.

(b) List the values of the signals generated by the control unit for `addi`. Explain the reasoning for any “don’t care” control signals. [10]

Branch: 0

MemRead: 0 (theoretically “don’t care” is the correct answer, but it should be false to prevent an exception or cache miss)

MemtoReg: 0

ALUOp: 10 (or simply “add”)

MemWrite: 0

ALUsrc: 1

RegWrite: 1

3. Let us assume that the clock period of the single-cycle processor shown in Figure 1 is 1000 ps. Consider the addition of a multiplier to the CPU. This addition will add 250 ps to the latency of the ALU, but will reduce the number of instructions by 4% (because there will no longer be a need to emulate the multiply instructions).

(a) What is the clock cycle time with this improvement? [5]

1250 ps ( $1000 + 250$ )

(b) What is the **speed** up achieved by adding this improvement? [5]

$1000 / (1250 * 0.96) = 0.83$ . Actually the performance is degraded.

(c) What is the longest delay by the newly added multiplier to result in performance improvement at least? [5]

Let us assume the additional delay by the multiplier is X. Then,  $1000 / ((1000+X)*0.96) \geq 1$ .  
The maximum value of X is  $40/0.96 = 41.67$  ps

4. Let us assume that you are requested to add a new instructions, `lwi.d rd, rs1, rs2` ("load with increment",  $R[rd] = M[R[rs1] + R[rs2]]$ ) to RISC-V. Explain how to figure out control signals of the single-cycle processor shown in Figure 1. [10]

Branch: 0

MemRead: 1

MemtoReg: 1

ALUOp: 10 (or simply "add")

MemWrite: 0

ALUsrc: 0

RegWrite: 1

5. Let us assume that you are requested to add additional branch instructions such as BNE (branch if not equal), BLT (branch if less than), and BGE (branch if greater or equal) in the single-cycle processor design in Lab #3. The following table shows the information of the branch instructions supported by the single-cycle processor.

Inst.	Description	opcode	funct3
BEQ	if ( $R[rs1] == R[rs2]$ ) $PC = PC + \{imm, 1'b0\}$	1100011	000
BNE	if ( $R[rs1] != R[rs2]$ ) $PC = PC + \{imm, 1'b0\}$		001
BLT	if ( $R[rs1] < R[rs2]$ ) $PC = PC + \{imm, 1'b0\}$		100
BGE	if ( $R[rs1] \geq R[rs2]$ ) $PC = PC + \{imm, 1'b0\}$		101

Assume that the values in `rs1` and `rs2` are all *signed* values and overflows/underflows do not happen in ALU. We add the signal (`branch_true`) that indicates the condition of a branch instruction is true. Complete the following SystemVerilog snippet to support the branch instructions in the above table. (Hint: you should use `alu_result` to check branch results.) [15]

```
logic      branch, branch_true;
logic      alu_zero;           // zero detection in ALU result
logic [63:0] alu_result;       // ALU result

assign branch = (opcode==7'b1100011) ? 1'b1: 1'b0;

always_comb begin
    case (funct3[2:0])
        3'b000: branch_true = alu_zero;
        3'b001: branch_true = ~alu_zero;           // ← FILL THIS
        3'b100: branch_true = alu_result[63];      // ← FILL THIS
        3'b101: branch_true = ~alu_result[63];     // ← FILL THIS
        default: branch_true = 1'b0;
```

```

    endcase
end

assign pc_next = (branch & branch_true) ? pc_next_branch: pc_next_plus4;

```

6. In this problem we examine how pipelining affects the clock cycle time of the processor. Problems in this exercise assume that individual stages of the datapath have the following latencies.

IF	ID	EX	MEM	WB
250 ps	400 ps	250 ps	300 ps	200 ps

Also, assume that instructions executed by this processor are broken down as follows.

ALU/logic	Jump/Branch	Load	Store
45%	20%	20%	15%

(a) What is the clock cycle time in a pipelined and non-pipelined processor? [5]

Pipelined processor: 400 ps. Non-pipelined processor: 1400 ps

(b) What is the total latency of an ld instruction in a pipelined and non-pipelined processor? [5]

Pipelined processor: 2000 ps since all instructions pass through all stages. Non-pipelined processor: 1400 ps.

(c) If we can split one stage of the pipelined datapath into two new stages, each with half the latency of the original stage, which stage would split and what is the new clock cycle time of the processor? [5]

ID stage should be split since it has the longest delay. New clock cycle time is 300 ps.

(d) Assuming there are no stalls or hazards, what is the utilization of the data memory? [5]

Load and store touch data memory, therefore 35%

(e) Assuming there are no stalls or hazards, what is the utilization of the write-register port of the register file? [5]

ALU/logic and load instructions write data to RF, therefore 65%

7. What is the minimum number of cycles needed to completely execute  $N$  instructions on a CPU with  $K$  stage pipeline? Justify your formula. [5]

$N + K - 1$ . Let's look at when each instruction is in the WB stage. In a  $K$ -stage pipeline, the first instruction does not enter the WB stage until cycle  $K$ . From that point on, at most one of the remaining  $N - 1$  instructions is in the WB stage during every cycle.

8. Add “NOP” (No operation) instructions to the code below so that it will run correctly on the 5-stage pipelined processor which we learned during the classes. Answer for the following conditions of the hardware supports.

```
ld x4, 0(x5)
add x11, x4, x6
add x11, x11, x11
add x12, x11, x4
```

(a) The processor does not handle data hazards. Only *internal forwarding* inside of the register file is supported. [8]

```
ld x4, 0(x5)
NOP
NOP
add x11, x4, x6
NOP
NOP
add x11, x11, x11
NOP
NOP
add x12, x11, x4
```

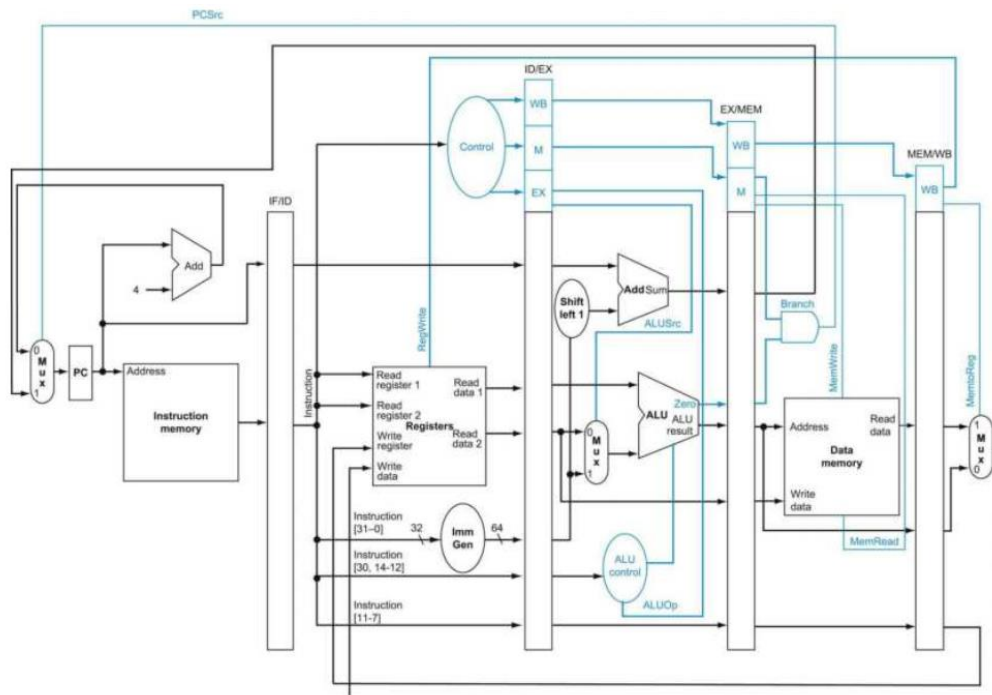

(b) The processor does not handle data hazards. The processor supports the data forwarding from *MEM/WB pipeline register* and *internal forwarding* inside the register file. [8]

```
ld x4, 0(x5)
NOP
add x11, x4, x6
NOP
add x11, x11, x11
NOP
add x12, x11, x4
```

(c) The processor does not handle data hazards. The processor supports the data forwarding from *EX/MEM and MEM/WB pipeline registers* and *internal forwarding* inside the register file. [8]

```
ld x4, 0(x5)
NOP
add x11, x4, x6
add x11, x11, x11
add x12, x11, x4
```

9. Consider the following 5-stage pipelined processor architecture. (See Figure 4.49 in the textbook) We will use this processor architecture as a baseline. Namely, branch instructions are resolved in EX stage and the result of a branch instruction is transferred in MEM stage. Assume that the hazard detection unit is implemented to detect hazard conditions and control pipelining of the processor.

Let us assume that the following assembly code is executed in the 5-stage pipelined processor. Assume that the branch instruction (beq) is taken.

```
ld    x29, 12(x16)
ld    x30, 8(x16)
sub   x30, x29, x30
beq   x30, x5, label
add   x15, x11, x14
and   x14, x4, x5
label: sub x15, x30, x14
```

(a) Assume that only internal forwarding inside of the register file is supported and no data forwarding is supported from the pipeline registers. Draw a pipeline diagram to show where the code above will stall. Indicate flushes as "---". [10]

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ld x29	IF	ID	EX	ME	WB										
ld x30		IF	ID	EX	ME	WB									
sub x30			IF	ID	ID	ID	EX	ME	WB						
beq x30				IF	IF	IF	ID	ID	ID	EX	ME	WB			
add x15							IF	IF	IF	ID	EX	---			
and x14										IF	ID	---			
sub x15											IF	IF	ID	EX	ME

(b) Assume that data forwarding is supported from MEM/WB pipeline register and internal forwarding is supported inside of the register file. Draw a pipeline diagram to show where the code above will stall. Indicate flushes as “---”. [10]

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ld x29	IF	ID	EX	ME	WB										
ld x30		IF	ID	EX	ME	WB									
sub x30			IF	ID	ID	EX	ME	WB							
beq x30				IF	IF	ID	ID	EX	ME	WB					
add x15						IF	IF	ID	EX	---					
and x14								IF	ID	---					
sub x15									IF	IF	ID	EX	ME	WB	

(c) Assume that data forwarding is supported from EX/MEM and MEM/WB pipeline registers and internal forwarding inside of the register file is supported. Draw a pipeline diagram to show where the code above will stall. Indicate flushes as “---”. [10]

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ld x29	IF	ID	EX	ME	WB										
ld x30		IF	ID	EX	ME	WB									
sub x30			IF	ID	ID	EX	ME	WB							
beq x30				IF	IF	ID	EX	ME	WB						
add x15						IF	ID	EX	---						
and x14							IF	ID	---						
sub x15								IF	IF	ID	EX	ME	WB		

(d) Assume that zero detection is performed using the data outputs from the register file in ID stage. Data forwarding is supported from EX/MEM and MEM/WB pipeline registers and internal forwarding inside of the register file is supported. Draw a pipeline diagram to show where the code above will stall. Indicate flushes as “---”. (Hint: you should consider data hazards caused by branch instructions.) [10]

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
ld x29	IF	ID	EX	ME	WB										
ld x30		IF	ID	EX	ME	WB									
sub x30			IF	ID	ID	EX	ME	WB							
beq x30				IF	IF	IF	IF	ID	EX	ME	WB				
add x15								IF	---						
and x14															
sub x15									IF	ID	EX	ME	WB		

10. If we change load/store instructions to use a register (without an offset) as the address, these instructions no longer need to use the ALU. As a result the MEM and EX stages can be overlapped and the pipeline has only 4 stages.

(a) How will the reduction in pipeline depth affect the clock cycle time? [5]

The clock period won't change because we don't make any changes to the slowest stage.

(b) How might this change improve the performance of the pipeline? [5]

The pipeline stalls caused by data hazards between load and following instructions that use the result of the loads will be removed. This can potentially reduce the number of stalls.

(c) How might this change degrade the performance of the pipeline? [5]

Removing the offset from loads and stores may increase the total number of instructions because some loads and stores will need additional add instructions to calculate addresses by displacement.

11. The importance of having a good branch predictor depends on how often conditional branches are executed. Together with branch predictor accuracy, this will determine how much time is spent stalling due to mispredicted branches. In this problem, let us assume that the breakdown of dynamic instructions into various instruction categories is as follows.

R-type	beq/bne	jal	ld	sd
40%	20%	5%	25%	10%

Also assume the following branch predictor accuracies.

Always-taken	Always-Not-Take	2-bit predictor
40%	60%	90%

(a) Stall cycles due to mispredicted branches increase the CPI. What is the extra CPI due to mispredicted branches with the always-taken predictor? Assume that branch outcomes are determined in the ID stage and applied in the EX stage that there are no data hazards, and that no delay slots are used. [5]

If a conditional branch instruction (beq/bne) is mispredicted, it will waste 2 cycles since the instructions currently in the IF and ID stages will be flushed. With the “always-taken” branch predictor, 60% of the conditional branches are mispredicted. The increased CPI is  $1 + (0.6 \times 0.2 \times 2) = 1.24$

(b) Repeat the above problem for the “always-not-taken” predictor. [5]

The increased CPI is  $1 + (0.4 \times 0.2 \times 2) = 1.16$

(c) Repeat the above problem for the 2-bit predictor. [5]

The increased CPI is  $1 + (0.1 \times 0.2 \times 2) = 1.04$

12. Consider the following C code:

```
for (i = 0; i < 100; i++)    // 1st loop
    for (j = 0; j < 100; j++) // 2nd loop
        .....
```

Let us assume that there are no conditional branches inside of the loops. When this C code is compiled, the conditional branch instructions are at the end of the loops. If the branch is taken the program jumps to the beginning of the loop.

(a) Let us assume that **one-bit** branch predictors are applied for the both loops. Calculate the hit ratio (%) of each branch predictor. The branch predictors are initialized as “0” (NOT TAKEN), and each branch predictor can be distinguished by program counter. [10]

For the first loop: miss (NT/T) – hit (T/T) - ..... - miss (T/NT), thus  $98/100 = 0.98$ , 98%

For the second loop: miss (NT/T) – hit (T/T) - ..... - miss (T/NT), thus  $98/100 = 0.98$ , 98%

Total hit ratio is 98%

(2) Let us assume that two-bit branch predictors are applied for the both loops. Calculate the hit ratio (%) of each branch predictor. The branch predictors are initialized as “00” (not taken), and each branch predictor can be distinguished by program counter. For the two-bit predictor, states “00” and “01” are predicted as “NOT TAKEN” and states “10” and “11” are predicted as “TAKEN”. [10]

For the first loop: miss (NT/T) – miss (NT/T) – hit (T/T) - ..... - miss (T/NT), thus  $97/100$ , 97%

For the second loop:

- The first iteration: miss (NT/T) – miss (NT/T) – hit (T/T) - ..... - miss (T/NT), thus  $97/100$

- Since the second iteration: hit (T/T) – hit (T/T) - ..... - miss (T/NT),  $99/100$

Therefore, total hit ratio =  $(97 + 99 \times 99) / 10000 = 0.9898$ , 98.98%
